

Research Question *q* **Connectomics**

“How does the **human structural connectome**¹ achieve integration of distributed functional subnetworks despite low global connection density and spatial constraints on axonal projections?”

Background Survey *b*

“[...] **Community detection**² algorithms (e.g. **Louvain**³, link community) identify overlapping node clusters with sparse inter-connections. However, these methods fail to capture higher-order transitive structures.”

Inspiration Document *i** **Network Physics**

“The notion of ***k*-clique**⁴ percolation in **random graphs**⁵ is introduced, where *k* is the size of the complete subgraphs whose large scale organizations are analytically and numerically investigated. [...] We discuss why **clique percolation**⁶ is a novel and efficient approach to the **identification of overlapping communities**⁷ in large real networks.”
